# OBLIQUE PROJECTION METHODS FOR LINEAR SYSTEMS WITH MULTIPLE RIGHT-HAND SIDES* 

K. JBILOU ${ }^{\dagger}$, H. SADOK ${ }^{\ddagger}$, AND A. TINZEFTE ${ }^{\S}$

#### Abstract

In the present paper, we describe new Lanczos-based methods for solving nonsymmetric linear systems of equations with multiple right-hand sides. These methods are based on global oblique projections of the initial residual onto a matrix Krylov subspace. We first derive the global Lanczos process to construct biorthonormal bases and we give some of its properties. Then we introduce new methods such as the global BCG and the global BiCGSTAB algorithms. Look-ahead versions of these algorithms are also given. Finally numerical examples will be given.

Key words. Global Lanczos, matrix Krylov subspace, block methods, iterative methods, nonsymmetric linear systems, multiple right-hand sides

1. Introduction. In many applications, we have to solve a few linear systems of equations with the same coefficient matrix and different right-hand sides. This is the case, for example, in numerical simulation of wave propagation. When all the right hand sides are available simultaneously, the problem we are concerned with can be expressed as

$$
\begin{equation*}
A X=B \tag{1.1}
\end{equation*}
$$

where $A$ is an $N \times N$ real nonsymmetric matrix, $B=\left[b_{1}, b_{2}, \ldots, b_{s}\right]$ and $X=\left[x_{1}, x_{2}, \ldots, x_{s}\right]$ are rectangular matrices of order $N \times s$ with $s \ll N$.

For nonsymmetric problems, several block Krylov subspace methods have been developed during the last years. The most popular methods are the block-biconjugate gradient (Bl-BCG) method [11, 17], the block-generalized minimum residual (BGMRES) algorithm $[14,20]$, the block-quasi-minimal residual (Bl-QMR) algorithm $[8,10]$ and the blockbiconjugate gradient stabilized (Bl-BiCGSTAB) method [6]. We note that block-methods require a deflation procedure to detect and delete linearly or almost linearly dependent vectors in the block Krylov subspaces generated during the iterations; see [8] for details.

The matrix equation (1.1) can also be solved by applying a method for a single-vector right-hand side to one of the columns, say $b_{q}, q \in\{1, \ldots, s\}$, of $B$ and solving the linear system

$$
A x_{q}=b_{q} .
$$

The preceding linear system is refereed as a seed system. The residuals of the other systems with a single right-hand side are then projected onto the Krylov subspace associated with the seed system. This procedure has been used in $[4,18,19]$. This technique is especially attractive when the right-hand sides $b_{j}, j=1, \ldots, s$ of (1.1) are not available at the same time; see for example [12, 21].

In the present paper, we use a third approach for solving the problem (1.1). This approach, which we previously used to define the global GMRES algorithm [9], is based on

[^0]oblique projections onto a matrix Krylov subspace and allows us to define the global Lanczos procedure that will be used to obtain the global Lanczos algorithm. We introduce global Lanczos-based algorithms, such as the global biconjugate gradient (Gl-BCG) algorithm, the global BiCGSTAB algorithm and look-ahead versions of these algorithms.

The paper is organized as follows. In Section 2, we introduce the global Lanczos process with some properties. In Section 3, we describe the global BCG algorithm and give some techniques for curing breakdowns. Section 4 is devoted to the global BiCGSTAB method with a look-ahead version. Finally, in Section 5 we give some numerical examples.

In the last section, we give some numerical examples to show the effectiveness of these new methods.

Throughout this paper, we use the following notations. For two matrices $X$ and $Y$ in $\mathbb{R}^{N \times s}$, we define the inner product $<X, Y>_{F}=\operatorname{tr}\left(X^{T} Y\right)$, where $\operatorname{tr}(Z)$ denotes the trace of the square matrix $Z$ and $X^{T}$ the transpose of the matrix $X$. The associated norm is the Frobenius norm which we denote by $\|.\|_{F}$. For a matrix $V \in \mathbb{R}^{N \times s}$, the matrix Krylov subspace $\mathcal{K}_{k}(A, V)$ is the subspace of $\mathbb{R}^{N \times s}$ generated by the matrices $V, A V, \ldots, A^{k-1} V$. A system of matrices of $\mathbb{R}^{N \times s}$ is said to be F-orthogonal if it is orthogonal with respect to the inner product $<,, .>_{F}$.
2. The global Lanczos process. Let $V$ be an $N \times s$ real matrix and denote by $\mathcal{K}_{k}(A, V)$ the matrix Krylov subspace of $\mathbb{R}^{N \times s}$ spanned by $V, A V, \ldots, A^{k-1} V$. Note that

$$
Z \in \mathcal{K}_{k}(A, V) \Longleftrightarrow Z=\sum_{i=1}^{k} \alpha_{i} A^{i-1} V ; \quad \alpha_{i} \in \mathbb{R} ; i=1, \ldots, k
$$

In other words $\mathcal{K}_{k}(A, V)$ is the subspace of $\mathbb{R}^{N \times s}$ of all $N \times s$ matrices which can be written as $Z=P(A) V$, where $P$ is a polynomial of degree not exceeding $k-1$. This means that each column of $Z$ is associated with one Krylov subspace.

Remark also that the matrix Krylov subspace $\mathcal{K}_{k}(A, V)$ is quite different from the block Krylov subspace $\tilde{\mathcal{K}}_{k}(A, V)$ used in block methods. In fact

$$
Z \in \tilde{\mathcal{K}}_{k}(A, V) \Longleftrightarrow Z=\sum_{i=1}^{k} A^{i-1} V \Omega_{i} ; \quad \Omega_{i} \in \mathbb{R}^{s \times s}, i=1, \ldots, k
$$

In this case, each column of $Z$ is associated with a sum of $s$ Krylov subspaces.
The minimal polynomial of $A$ for $V$ is the nonzero monic polynomial of lowest degree such that $P(A) V=0$. The degree $m$ of this polynomial does not exceed $N$. We have the following result which is easy to prove.

Proposition 2.1. Let $m$ be the degree of the minimal polynomial of $A$ for $V$. Then we have
(1) $\mathcal{K}_{m}(A, V)$ is invariant under $A$.
(2) $\operatorname{dim}\left(\mathcal{K}_{k}(A, V)\right)=\min (k, m)$.

Let $V_{1}$ and $W_{1}$ be two $N \times s$ matrices and denote by $\mathcal{K}_{k}\left(A, V_{1}\right)$ and $\mathcal{K}_{k}\left(A^{T}, W_{1}\right)$ the matrix Krylov subspaces generated by $\left\{V_{1}, A V_{1}, \ldots, A^{(k-1)} V_{1}\right\}$ and $\left\{W_{1}, A^{T} W_{1}, \ldots, A^{T(k-1)}\right.$ $\left.W_{1}\right\}$, respectively.

The global Lanczos process constructs a pair of two global biorthogonal bases $\left\{V_{1}, V_{2}\right.$, $\left.\ldots, V_{k}\right\}$ and $\left\{W_{1}, W_{2}, \ldots, W_{k}\right\}$ of the matrix Krylov subspaces $\mathcal{K}_{k}\left(A, V_{1}\right)$ and $\mathcal{K}_{k}\left(A^{T}, W_{1}\right)$, respectively, such that

$$
<V_{i}, W_{j}>_{F}=\operatorname{tr}\left(V_{i}^{T} W_{j}\right)=\delta_{i j} ; i, j=1, \ldots, k
$$

The algorithm is defined as follows:

## ALGORITHM 1 The global Lanczos process

1. Choose two $N \times s$ matrices $V_{1}$ and $W_{1}$ such that $\left\langle V_{1}, W_{1}\right\rangle_{F}=1$,
2. set $\beta_{1}=\delta_{1}=0$ and $W_{0}=V_{0}=0$,
3. for $j=1,2, \ldots, k$
$\alpha_{j}=\operatorname{tr}\left(W_{j}^{T} A V_{j}\right)$,
$\tilde{V}_{j+1}=A V_{j}-\alpha_{j} V_{j}-\beta_{j} V_{j-1}$,
$\tilde{W}_{j+1}=A^{T} W_{j}-\alpha_{j} W_{j}-\delta_{j} W_{j-1}$,
$\delta_{j+1}=\mid \operatorname{tr}\left(\left.\tilde{V}_{j+1}^{T} \underset{\tilde{V}_{j+1}}{\tilde{W}_{j+1}}\right|^{1 / 2}\right.$,
$\beta_{j+1}=\operatorname{tr}\left(\tilde{V}_{j+1}^{T} \tilde{W}_{j+1}\right) / \delta_{j+1}$,
$V_{j+1}=\tilde{V}_{j+1} / \delta_{j+1}$,
$W_{j+1}=\tilde{W}_{j+1} / \beta_{j+1}$,
end.
Note that a breakdown occurs in the algorithm if, for some $j, \operatorname{tr}\left(\tilde{V}_{j+1}^{T} \tilde{W}_{j+1}\right)=0$. If $\tilde{V}_{j+1}=0$ for some $j$, then the matrix Krylov subspace $\mathcal{K}_{j}\left(A, V_{1}\right)$ is invariant under $A$ and then $j \geq m$ the degree of the minimal polynomial of $A$ for $V_{1}$. We will see that in this case we obtain the exact solution of the problem (1.1).

Below we will give a look-ahead Lanczos-type algorithm that avoids the breakdown. Note that, since Algorithm 1 does not involve matrix inversions, the problem of linear dependence of vectors in the sequences $V_{1}, A V_{1}, \ldots$ and $W_{1}, A^{T} W_{1}, \ldots$ is not an issue. Therefore no deflation procedure to delete linearly or almost linearly dependent vectors is required. From now on, we set $\mathcal{V}_{k}=\left[V_{1}, \ldots, V_{k}\right]$ and $\mathcal{W}_{k}=\left[W_{1}, \ldots, W_{k}\right]$, two matrices of dimension $N \times k s$. Let $T_{k}$ be the tridiagonal matrix of dimension $k \times k$ defined as:

$$
T_{k}=\left[\begin{array}{cccc}
\alpha_{1} & \beta_{2} & & \\
\delta_{2} & \alpha_{2} & \ddots & \\
& \ddots & \ddots & \beta_{k} \\
& & \delta_{k} & \alpha_{k}
\end{array}\right]
$$

where $\alpha_{i}, \beta_{i}$ and $\delta_{i}$ are the scalars defined in the Algorithm 1.
Note that, for the Block Lanczos algorithm, the corresponding matrix is a block-tridiagonal matrix of dimension $k s \times k s$.
Define the matrix

$$
\tilde{T}_{k}=\left[\begin{array}{c}
T_{k} \\
\delta_{k+1} e_{k}^{T}
\end{array}\right]
$$

where $e_{k}=(0, \ldots, 0,1)^{T} \in \mathbb{R}^{k}$.
We use the notation $*$ defined in [9] for the following product

$$
\begin{equation*}
\mathcal{V}_{k} * y=\sum_{i=1}^{k} y^{i} V_{i}=\mathcal{V}_{k}\left(y \otimes I_{s}\right) \tag{2.1}
\end{equation*}
$$

where $y=\left(y^{1}, y^{2}, \ldots, y^{k}\right)^{T}$ is a vector of $\mathbb{R}^{k}$, and analogously

$$
\begin{equation*}
\mathcal{V}_{k} * T_{k}=\left[\mathcal{V}_{k} * T_{., 1}, \mathcal{V}_{k} * T_{., 2}, \ldots, \mathcal{V}_{k} * T_{., k}\right] \tag{2.2}
\end{equation*}
$$

where $T_{., i}$ denotes the $i$-th column of the matrix $T_{k}$.

Using these notations, we have the following result.
Proposition 2.2. Assume that the global Lanczos algorithm does not break down before $k$ steps. Then $\left\{V_{1}, \ldots, V_{k}\right\}$ and $\left\{W_{1}, \ldots, W_{k}\right\}$ form bases of the matrix Krylov subspaces $\mathcal{K}_{k}\left(A, V_{1}\right)$ and $\mathcal{K}_{k}\left(A^{T}, W_{1}\right)$, respectively, and we have the following relations :

$$
\begin{gather*}
A \mathcal{V}_{k}=\mathcal{V}_{k} * T_{k}+\delta_{k+1}\left[0, \ldots, 0, V_{k+1}\right]  \tag{2.3}\\
A \mathcal{V}_{k}=\mathcal{V}_{k+1} * \tilde{T}_{k} \tag{2.4}
\end{gather*}
$$

Proof. From the definition of the product * and the structure of the matrix $T_{k}$, we have for $j=1, \ldots, k-1$,

$$
\begin{aligned}
\mathcal{V}_{k} * T_{., j} & =\alpha_{j} V_{j}+\delta_{j+1} V_{j+1}+\beta_{j} V_{j-1} \\
& =A V_{j}
\end{aligned}
$$

and

$$
\begin{aligned}
\mathcal{V}_{k} * T_{., k} & =\beta_{k} V_{k-1}+\alpha_{k} V_{k} \\
& =A V_{k}+\delta_{k+1} V_{k+1}
\end{aligned}
$$

Then we obtain

$$
A \mathcal{V}_{k}=\mathcal{V}_{k} * T_{k}+\delta_{k+1}\left[0, \ldots, 0, V_{k+1}\right]
$$

For the relation (2.4), we have

$$
\begin{aligned}
\mathcal{V}_{k+1} * \tilde{T}_{k} & =\left[\mathcal{V}_{k}, V_{k+1}\right] * \tilde{T}_{k} \\
& =\mathcal{V}_{k} * T_{k}+\delta_{k+1} e_{k}^{T} V_{k+1} \\
& =\mathcal{V}_{k} * T_{k}+\delta_{k+1}\left[0, \ldots, 0, V_{k+1}\right]
\end{aligned}
$$

Hence, using the relation (2.3), the result of (2.4) holds.
Consider now the block linear system (1.1), let $X_{0}$ be an initial guess and let $R_{0}=B-$ $A X_{0}$ be the corresponding residual. The global Lanczos method for solving (1.1) generates, at step $k$, the iterate $X_{k}$ such that

$$
\begin{equation*}
X_{k}-X_{0}=Z_{k} \in \mathcal{K}_{k}\left(A, R_{0}\right) \tag{2.5}
\end{equation*}
$$

and

$$
\begin{equation*}
R_{k}=B-A X_{k} \perp_{F} \mathcal{K}_{k}\left(A^{T}, \tilde{R}_{0}\right) \tag{2.6}
\end{equation*}
$$

where $\tilde{R}_{0}$ is a given $N \times s$ matrix provided that, $<R_{0}, \tilde{R}_{0}>_{F} \neq 0$. Let $\mathcal{S}_{k}$ denote the oblique projector onto $A \mathcal{K}_{k}\left(A, R_{0}\right)$ and orthogonal to $\mathcal{K}_{k}\left(A^{T}, \tilde{R}_{0}\right)$. Then it follows from the relations (2.5) and (2.6) that

$$
\begin{equation*}
R_{k}=R_{0}-\mathcal{S}_{k} R_{0} \tag{2.7}
\end{equation*}
$$

Let $\left\{V_{1}, \ldots, V_{k}\right\}$ and $\left\{W_{1}, \ldots, W_{k}\right\}$ be the sets of matrices constructed by Algorithm 1, generating the matrix Krylov subspaces $\mathcal{K}_{k}\left(A, R_{0}\right)$ and $\mathcal{K}_{k}\left(A^{T}, \tilde{R}_{0}\right)$, respectively, with the
initializations $V_{1}=R_{0} /\left\|R_{0}\right\|_{F}$ and $W_{1}$ such that, $<V_{1}, W_{1}>_{F}=1$. Now, from the relation (2.5) it follows that,

$$
\begin{equation*}
X_{k}=X_{0}+\mathcal{V}_{k} * y_{k} \tag{2.8}
\end{equation*}
$$

where $y_{k}$ is the vector of $\mathbb{R}^{k}$ obtained from

$$
<R_{0}-A \mathcal{V}_{k} * y_{k}, W_{i}>_{F}=0
$$

which is equivalent to

$$
\begin{equation*}
<R_{0}, W_{i}>_{F}=<A \mathcal{V}_{k} * y_{k}, W_{i}>_{F} ; i=1, \ldots, k \tag{2.9}
\end{equation*}
$$

Hence, (2.9) can be written as

$$
\sum_{j=1}^{k} y_{k}^{j} \operatorname{tr}\left(W_{1}^{T} A V_{j}\right)=\left\|R_{0}\right\|_{F}
$$

and

$$
\sum_{j=1}^{k} y_{k}^{j} \operatorname{tr}\left(W_{i}^{T} A V_{j}\right)=0 ; i=2, \ldots, k
$$

Finally, the preceding linear system can be expressed as

$$
\begin{equation*}
T_{k} y_{k}=\left\|R_{0}\right\|_{F} e_{1}^{(k)} \tag{2.10}
\end{equation*}
$$

where $e_{1}^{(k)}$ is the first vector of the canonical basis of $\mathbb{R}^{k}$. If the tridiagonal matrix $T_{k}$ is nonsingular, the iterate $X_{k}$ obtained by the global Lanczos method is then given as

$$
\begin{equation*}
X_{k}=X_{0}+\left\|R_{0}\right\|_{F} \mathcal{V}_{k} * T_{k}^{-1} e_{1}^{(k)} \tag{2.11}
\end{equation*}
$$

Let us see now how to compute the norm of the residual $R_{k}$ without actually having to compute the approximation $X_{k}$. This will be useful for determining whether convergence is achieved without explicitly using $X_{k}$. The residual $R_{k}$ is given as

$$
R_{k}=R_{0}-A \mathcal{V}_{k} * y_{k}
$$

From the relation (2.3) and the fact that, $R_{0}=\left\|R_{0}\right\|_{F} V_{1}$, it follows that,

$$
R_{k}=\left\|R_{0}\right\|_{F} V_{1}-\mathcal{V}_{k} * T_{k} y_{k}+\delta_{k+1}\left[0,0, \ldots, V_{k+1}\right] * y_{k}
$$

On the other hand, since $V_{1}=\mathcal{V}_{k} * e_{1}^{(k)}$, we obtain

$$
R_{k}=\mathcal{V}_{k} *\left(\left\|R_{0}\right\|_{F} e_{1}^{(k)}-T_{k} y_{k}\right)+\delta_{k+1}\left[0,0, \ldots, V_{k+1}\right] * y_{k}
$$

Finally, using (2.11) in the preceding equation, we get

$$
\begin{equation*}
\left\|R_{k}\right\|_{F}=\left|\delta_{k+1} y_{k}^{k}\right|\left\|V_{k+1}\right\|_{F} \tag{2.12}
\end{equation*}
$$

where $y_{k}^{k}$ is the last component of the vector $y_{k}$. If $m$ is the degree of the minimal polynomial of $A$ for $R_{0}$, then $\mathcal{K}_{m}\left(A, R_{0}\right)$ is invariant and $X_{m}=X$ is the exact solution of (1.1). As $m \leq N$, the algorithm converges in at most $N$ iterations.

In what follows, we describe some global Lanczos-based methods for solving the multiple linear system (1.1).

## 3. The Global Biconjugate Gradient method.

3.1. The Global BCG algorithm. The Global Biconjugate Gradient (Gl-BCG) algorithm can be derived from Algorithm 1 in the same way as the classical BCG has been obtained in [7]. At step $k$, the residual $R_{k}$ generated by this algorithm is such that, $R_{k}-R_{0}$ lies in the right matrix Krylov subspace $\mathcal{K}_{k}\left(A, A R_{0}\right)=\operatorname{span}\left\{A R_{0}, A^{2} R_{0}, \ldots, A^{k} R_{0}\right\}$ and $R_{k}$ is F-orthognal to the left matrix Krylov subspace $\mathcal{K}_{k}\left(A^{T}, \tilde{R}_{0}\right)=\operatorname{span}\left\{\tilde{R}_{0}, A^{T} \tilde{R}_{0}, \ldots, A^{T^{k-1}}\right.$ $\left.\tilde{R}_{0}\right\}$, where $\tilde{R}_{0}$ is a given $N \times s$ matrix.

The algorithm is defined as follows

## ALGORITHM 2 The Global Biconjugate Gradient (GI-BCG) algorithm

1. Compute $R_{0}=B-A X_{0}$ for a given $X_{0}$, and choose $\tilde{R}_{0}$ such that, $<R_{0}, \tilde{R}_{0}>_{F} \neq 0$,
2. set $P_{0}=R_{0}$ and $\tilde{P}_{0}=\tilde{R}_{0}$,
3. for $j=0,1, \ldots$ compute
a. $X_{j+1}=X_{j}+\alpha_{j} P_{j}$, where $\alpha_{j}=\frac{<R_{j}, \tilde{R}_{j}>_{F}}{<A P_{j}, \tilde{P}_{j}>_{F}}$,
b. $R_{j+1}=R_{j}-\alpha_{j} A P_{j}$,
c. $\tilde{R}_{j+1}=\tilde{R}_{j}-\alpha_{j} A^{T} \tilde{P}_{j}$,
d. $P_{j+1}=R_{j+1}+\beta_{j} P_{j}$, where $\beta_{j}=\frac{<R_{j+1}, \tilde{R}_{j+1}>_{F}}{<R_{j}, \tilde{R}_{j}>_{F}}$,
e. $\tilde{P}_{j+1}=\tilde{R}_{j+1}+\beta_{j} \tilde{P}_{j}$.

It is not difficult to prove the next results.
PROPOSITION 3.1. The matrices produced by the Gl-BCG algorithm satisfy the following relations:
(1) $<R_{k}, \tilde{R}_{l}>_{F}=0$ and $<A P_{k}, \tilde{P}_{l}>_{F}=0 ; k \neq l$.
(2) $\operatorname{span}\left\{P_{0}, \ldots, P_{k}\right\}=\operatorname{span}\left\{R_{0}, \ldots, A^{k} R_{0}\right\}$.
(3) $\operatorname{span}\left\{\tilde{P}_{0}, \ldots, \tilde{P}_{k}\right\}=\operatorname{span}\left\{\tilde{R}_{0}, \ldots, A^{T^{k}} \tilde{R}_{0}\right\}$.
(4) $\quad R_{k}-R_{0} \in \mathcal{K}_{k}\left(A, R_{0}\right)$ and $R_{k}$ is orthogonal to $\mathcal{K}_{k}\left(A^{T}, \tilde{R}_{0}\right)$.

The residual $R_{k}$ produced by the Gl-BCG algorithm can also be expressed as

$$
R_{k}=\mathcal{P}_{k}(A) R_{0}
$$

where $\mathcal{P}_{k}$ is a polynomial of degree $k$ with scalar coefficients satisfying $\mathcal{P}_{k}(0)=1$. The matrix direction $P_{k}$ can also be written as

$$
P_{k}=\phi_{k}(A) R_{0}
$$

Here $\phi_{k}$ is a polynomial with scalar coefficients. Note that $\tilde{R}_{k}$ and $\tilde{P}_{k}$ also can be expressed as

$$
\tilde{R}_{k}=\mathcal{P}_{k}\left(A^{T}\right) \tilde{R}_{0} \text { and } \tilde{P}_{k}=\phi_{k}\left(A^{T}\right) \tilde{R}_{0}
$$

One disadvantage of the Gl-BCG algorithm is the fact that breakdowns may occur in the algorithm. In the following subsection we give a look-ahead Lanczos-type algorithm that avoids this problem.
3.2. A look-ahead global Lanczos-type algorithm. The global Lanczos method constructs a sequence of approximations $\left(X_{k}\right), k=1,2, \ldots$ such that,

$$
X_{k}-X_{0} \in \mathcal{K}_{k}\left(A, R_{0}\right)
$$

and

$$
R_{k} \perp_{F} \mathcal{K}_{k}\left(A^{T}, \tilde{R}_{0}\right)
$$

where $\tilde{R}_{0}$ and $X_{0}$ are chosen $N \times s$ matrices. Hence the residual $R_{k}$ satisfies

$$
R_{k}=\mathcal{P}_{k}(A) R_{0}
$$

where $\mathcal{P}_{k}$ is a scalar polynomial of degree at most $k$ with $\mathcal{P}_{k}(0)=1$. Then the F-orthogonality property gives

$$
<A^{T^{i}} \tilde{R}_{0}, R_{k}>_{F}=0 ; i=0, \ldots, k-1
$$

Setting $c_{i}=<\tilde{R}_{0}, A^{i} R_{0}>_{F}$ and defining $c$ to be the linear functional on the space of polynomials by $c\left(t^{i}\right)=c_{i}$, the orthogonality relation can be written as

$$
c\left(t^{i} \mathcal{P}_{k}(t)\right)=0 ; i=0, \ldots, k-1
$$

This shows that $\mathcal{P}_{k}$ is the polynomial of degree $k$ belonging to the family of orthogonal polynomials with respect to the functional $c$. The F-orthogonality property shows that the polynomial $\mathcal{P}_{k}$ exists and is unique if and only if the Hankel determinant

$$
\mathcal{H}_{k}^{(1)}=\left|\begin{array}{ccc}
c_{1} & \ldots & c_{k} \\
\vdots & & \vdots \\
c_{k} & \ldots & c_{2 k-1}
\end{array}\right| \neq 0
$$

Let $c^{(1)}$ be the linear functional defined on the space of polynomials by $c^{(1)}\left(t^{i}\right)=c\left(t^{i+1}\right)=$ $c_{i+1}$ and let $\mathcal{P}_{k}^{(1)}$ be the monic polynomial of degree $k$ belonging to the family of formal orthogonal polynomials with respect to $c^{(1)} . \mathcal{P}_{k}$ and $\mathcal{P}_{k}^{(1)}$ exist under the condition that $\mathcal{H}_{k}^{(1)} \neq 0$.

The recursive computation of $\mathcal{P}_{k}$ involves the computation of some scalar products which appear as denominators and of the recurrence relationships. Thus, if one of these scalar products vanishes, a breakdown occurs in the algorithm. This can be avoided by jumping over these polynomials and by computing only the existing ones (called regular). This kind of breakdown is called true breakdown [1]. There in another possible breakdown in Lanczostype algorithms (called ghost breakdown [1] which is not due to the non-existence of some orthogonal polynomials of the family $\mathcal{P}_{k}$, but to the recurrence relationship under consideration which cannot be used for computing $\mathcal{P}_{k}$, for some $k$. For instance, in Gl-Lanczos/Ortores ( $\mathcal{P}_{k+1}$ is computed from $\mathcal{P}_{k}$ and $\mathcal{P}_{k-1}$ ) and in Gl-Lanczos/orthomin (Gl-BICG) ( $\mathcal{P}_{k+1}$ is computed from $\mathcal{P}_{k}$ and $\mathcal{P}_{k}^{(1)}$, and the polynomial $\mathcal{P}_{k+1}^{(1)}$ is computed form $\mathcal{P}_{k+1}$ and $\mathcal{P}_{k}^{(1)}$ ). Since we are interested only on the existing polynomials (regular), we still denote by $\mathcal{P}_{k}$ and $\mathcal{P}_{k+1}$ two successive regular polynomials of degrees $n_{k}$ and $n_{k}+m_{k}$ where $m_{k}$ is the length of the jump. As shown in [5], $m_{k}$ is defined such that,

$$
c^{(1)}\left(t^{i} \mathcal{P}_{k}^{(1)}\right)=0 ; \quad i=0, \ldots, n_{k}+m_{k}-2
$$

and

$$
c^{(1)}\left(t^{n_{k}+m_{k}-1} \mathcal{P}_{k}^{(1)}\right) \neq 0
$$

The polynomials $\mathcal{P}_{k+1}$ et $\mathcal{P}_{k+1}^{(1)}$ are computed by the following recursive relations

$$
\begin{aligned}
& \mathcal{P}_{k+1}(t)=\mathcal{P}_{k}(t)-t w_{k}(t) \mathcal{P}_{k}^{(1)}(t) \\
& \mathcal{P}_{k+1}^{(1)}(t)=q_{k}(t) \mathcal{P}_{k}^{(1)}(t)-C_{k+1} P_{k-1}^{(1)}(t)
\end{aligned}
$$

where $\mathcal{P}_{-1}^{(1)}(t)=0, C_{1}=0$ and $\mathcal{P}_{0}^{(1)}(t)=1$. Here $q_{k}$ is a monic polynomial of degree $m_{k}$ and $w_{k}$ is a polynomial of degree at most $m_{k}-1$.
If we set

$$
R_{k}=\mathcal{P}_{k}(A) R_{0} \quad \text { and } \quad Z_{k}=\mathcal{P}_{k}^{(1)}(A) R_{0}
$$

then we get the following relations

$$
\begin{aligned}
R_{k+1} & =R_{k}-A w_{k}(A) Z_{k} \\
X_{k+1} & =X_{k}-w_{k}(A) Z_{k} \\
Z_{k+1} & =q_{k}(A) Z_{k}-C_{k+1} Z_{k-1}
\end{aligned}
$$

with the initializations $Z_{0}=R_{0}, Z_{-1}=0$ and $C_{1}=0$. The scalars $C_{k+1}$ and the coefficients of the polynomials $q_{k}$ and $w_{k}$ are computed using the orthogonality relations of the polynomials $\mathcal{P}_{k+1}$ and $\mathcal{P}_{k+1}^{(1)}$. Since $\mathcal{P}_{k}^{(1)}$ is of degree exactly $n_{k}$ these orthogonality relations can be expressed as follows

$$
\begin{aligned}
c\left(t^{i} \mathcal{P}_{k}^{(1)} \mathcal{P}_{k+1}\right) & =0 ; \quad i=0, \ldots, m_{k}-1 \\
c^{(1)}\left(t^{i} \mathcal{P}_{k}^{(1)} \mathcal{P}_{k+1}^{(1)}\right) & =0 ; \quad i=0, \ldots, m_{k}-1
\end{aligned}
$$

and

$$
\begin{aligned}
c^{(1)}\left(t^{i} \mathcal{P}_{k}^{(1)^{2}}\right) & =0 ; \quad i=0, \ldots, m_{k}-2 \\
c^{(1)}\left(t^{m_{k}-1}{\mathcal{P}_{k}^{(1)^{2}}}^{2}\right) & \neq 0
\end{aligned}
$$

Let

$$
\tilde{Z}_{k}=\mathcal{P}_{k}^{(1)}\left(A^{T}\right) \tilde{R}_{0}
$$

Then we have the recurrence relation

$$
\tilde{Z}_{k+1}=q_{k}\left(A^{T}\right) \tilde{Z}_{k}-C_{k+1} \tilde{Z}_{k-1}
$$

with $\tilde{Z}_{0}=\tilde{R}_{0}$ et $\tilde{Z}_{-1}=0$. The length of the jump $m_{k}$, is computed by using the following relations

$$
<\tilde{Z}_{k}, A^{i+1} Z_{k}>_{F}=0 \text { for } i=0, \ldots, m_{k}-2 \text { and }<\tilde{Z}_{k}, A^{m_{k}} Z_{k}>_{F} \neq 0
$$

Let $w_{k}(t)=\sum_{i=0}^{m_{k}-1} \beta_{i}^{(k)} t^{i}$ and $q_{k}(t)=\sum_{i=0}^{m_{k}} \alpha_{i}^{(k)} t^{i}$ with $\alpha_{m_{k}}^{(k)}=1$, and define

$$
\begin{aligned}
d_{i}^{(k)} & =<\tilde{Z}_{k}, A^{i} R_{k}>_{F} ; \quad i=0, \ldots, m_{k}-1 \\
b_{i}^{(k)} & =<\tilde{Z}_{k}, A^{m_{k}+i} Z_{k}>_{F} ; \quad i=0, \ldots, m_{k}
\end{aligned}
$$

The coefficients $\alpha_{i}^{(k)}$ and $\beta_{i}^{(k)}, i=0, \ldots, m_{k}-1$, are given as solutions of the following two triangular linear systems with the same coefficient matrix

$$
\left[\begin{array}{cccccc}
b_{0}^{(k)} & & & & & \\
b_{1}^{(k)} & b_{0}^{(k)} & & & 0 & \\
\vdots & b_{1}^{(k)} & \ddots & & & \\
\vdots & \vdots & \ddots & \ddots & & \\
b_{m_{k}-2}^{(k)} & b_{m_{k}-1}^{(k)} & \cdots & \ddots & b_{0}^{(k)} & \\
b_{m_{k}-1}^{(k)} & b_{m_{k}-2}^{(k)} & \cdots & \cdots & b_{1}^{(k)} & b_{0}^{(k)}
\end{array}\right]\left[\begin{array}{cc}
\beta_{m_{k}-1}^{(k)} & \alpha_{m_{k-1}}^{(k)} \\
\beta_{m_{k}-2}^{(k)} & \alpha_{m_{k}-2}^{(k)} \\
\vdots & \vdots \\
\vdots & \vdots \\
\beta_{1}^{(k)} & \alpha_{1}^{(k)} \\
\beta_{0}^{(k)} & \alpha_{0}^{(k)}
\end{array}\right]=\left[\begin{array}{cc}
d_{0}^{(k)} & -b_{1}^{(k)} \\
d_{1}^{(k)} & -b_{2}^{(k)} \\
\vdots & \vdots \\
\vdots & \vdots \\
d_{m_{k}-2}^{(k)} & -b_{m_{k}-1}^{(k)} \\
d_{m_{k}-1}^{(k)} & -b_{m_{k}}^{(k)}
\end{array}\right] .
$$

As $b_{0}^{(k)}=<\tilde{Z}_{k}, A^{m_{k}} Z_{k}>_{F} \neq 0$, the matrix of the preceding system is always nonsingular. We also note that, $C_{k+1}=b_{0}^{(k)} / b_{0}^{(k-1)}$. Summarizing we get the following algorithm:

ALGORITHM 3 Global mrz-stab $\left(A, B, X_{0}, \tilde{R}_{0}\right)$

1. initialization

$$
\begin{aligned}
& Z_{-1}=0, \tilde{Z}_{-1}=0, R_{0}=B-A X_{0}, Z_{0}=R_{0}, \tilde{Z}_{0}=\tilde{R}_{0} \\
& n_{0}=0, C_{1}=0, m_{-1}=0 \text { and } k=0,
\end{aligned}
$$

2. while $R_{k} \neq 0$ do

$$
\begin{aligned}
& Z_{k, 0}=Z_{k}, \tilde{Z}_{k, 0}=\tilde{Z}_{k}, d_{0}^{(k)}=<\tilde{Z}_{k, 0}, R_{k}>_{F} \\
& Z_{k, 1}=A Z_{k, 0}, m_{k}=1, b_{0}^{(k)}=<\tilde{Z}_{k, 0}, Z_{k, 1}>_{F}
\end{aligned}
$$

3. while $b_{0}^{(k)}=0$ do
$m_{k}=m_{k}+1, Z_{k, m_{k}}=A Z_{k, m_{k}-1}, b_{0}^{(k)}=<\tilde{Z}_{k, 0}, Z_{k, m_{k}}>_{F}$,
end while
4. $\quad \beta_{m_{k}-1}^{(k)}=d_{0}^{(k)} / b_{0}^{(k)}$
if $k \neq 0 \quad$ then $C_{k+1}=b_{0}^{(k)} / b_{0}^{(k-1)}$,
end if
5. for $i=1, \cdots, m_{k}$ do

$$
\begin{aligned}
& \tilde{Z}_{k, i}=A^{T} \tilde{Z}_{k, i-1} \\
& b_{i}^{(k)}=<\tilde{Z}_{k, i}, Z_{k, m_{k}}>_{F} \\
& \text { if } \quad i \neq m_{k} \text { then } \\
& \quad d_{i}^{(k)}=<\tilde{Z}_{k, i}, R_{k}>_{F} \\
& \text { compute } \beta_{m_{k}-i-1}^{(k)} \\
& \text { end if } \\
& \text { compute } \alpha_{m_{k}-i}^{(k)} \\
& \text { end for }
\end{aligned}
$$

6. $\quad X_{k+1}=X_{k}+\beta_{0}^{(k)} Z_{k, 0}+\beta_{1}^{(k)} Z_{k, 1}+\cdots+\beta_{m_{k}-1}^{(k)} Z_{k, m_{k}-1}$

$$
\begin{aligned}
R_{k+1} & =R_{k}-\left[\beta_{0}^{(k)} Z_{k, 1}+\beta_{1} Z_{k, 2}+\cdots+\beta_{m_{k}-1}^{(k)} Z_{k, m_{k}}\right] \\
Z_{k+1} & =\alpha_{0}^{(k)} Z_{k, 0}+\alpha_{1}^{(k)} Z_{k, 1}+\cdots+\alpha_{m_{k}-1}^{(k)} Z_{k, m_{k}-1}+Z_{k, m_{k}}-C_{k+1} Z_{k-1} \\
\tilde{Z}_{k+1} & =\alpha_{0}^{(k)} \tilde{Z}_{k, 0}+\alpha_{1}^{(k)} \tilde{Z}_{k, 1}+\cdots+\alpha_{m_{k}-1}^{(k)} \tilde{Z}_{k, m_{k}-1}+\tilde{Z}_{k, m_{k}}-C_{k+1} \tilde{Z}_{k-1}
\end{aligned}
$$

7. $n_{k+1}=n_{k}+m_{k}$
$k=k+1$
end while

The computation of the global MRZ-stab algorithm requires the storage of many matrices of dimension $N \times s$. To overcome this problem, we use Horner's algorithm to compute $w_{k}(A) R_{k}$ and $q_{k}(A) Z_{k}$. Let $h_{k}$ be the monic polynomial defined by

$$
h_{k}(t)=\gamma_{0}^{(k)}+\ldots+\gamma_{m_{k}-1}^{(k)} t^{m_{k}-1}+t^{m_{k}}
$$

Then applying Horner's algorithm, the polynomial $h_{k}$ can be computed recursively as follows

$$
\begin{aligned}
h_{k}^{(0)} & =1 \\
h_{k}^{(i)} & =t h_{k}^{(i-1)}+\gamma_{m_{k}-i}^{(k)} \quad \text { for } i=1, \ldots, m_{k} \\
h_{k}(t) & =h_{k}^{\left(m_{k}\right)}(t)
\end{aligned}
$$

The coefficients $\gamma_{i}^{(k)}, i=1, \ldots, m_{k}$, are computed such that,

$$
\left[\begin{array}{cccccc}
b_{0}^{(k)} & & & & \\
b_{1}^{(k)} & b_{0}^{(k)} & & & 0 & \\
\vdots & b_{1}^{(k)} & \ddots & & & \\
\vdots & \vdots & \ddots & \ddots & & \\
b_{m_{k}-2}^{(k)} & b_{m_{k}-1}^{(k)} & \cdots & \ddots & b_{0}^{(k)} & \\
b_{m_{k}-1}^{(k)} & b_{m_{k}-2}^{(k)} & \cdots & \ldots & b_{1}^{(k)} & b_{0}^{(k)}
\end{array}\right]\left[\begin{array}{c}
\gamma_{m_{k}-1}^{(k)} \\
\gamma_{m_{k}-2}^{(k)} \\
\vdots \\
\vdots \\
\gamma_{1}^{(k)} \\
\gamma_{0}^{(k)}
\end{array}\right]=-\left[\begin{array}{c}
b_{1}^{(k)} \\
b_{2}^{(k)} \\
\vdots \\
\vdots \\
b_{m_{k}-1}^{(k)} \\
b_{m_{k}}^{(k)}
\end{array}\right] .
$$

Then using the expressions of the coefficients $\beta_{i}^{(k)}$ and $\alpha_{i}^{(k)}$, one obtains

$$
\begin{aligned}
w_{k}(t) & =\frac{1}{b_{0}^{(k)}} \sum_{j=0}^{m_{k}-1} d_{m_{k}-j-1}^{(k)} h_{k}^{(j)}(t) \\
q_{k}(t) & =h_{k}(t)=h_{k}^{\left(m_{k}\right)}(t)
\end{aligned}
$$

Note that, with this new approach, we do not have to store all the $b_{i}^{(k)}$,s but only $b_{0}^{(k)}$. The new algorithm is called global HMRZ-stab and is summarized as follows.

## ALGORITHM 4 Global HMRZ-stab $\left(A, B, X_{0}, \tilde{R}_{0}\right)$

1. initialization

$$
\begin{aligned}
& Z_{-1}=0, \quad \tilde{Z}_{-1}=0 \\
& R_{0}=B-A X_{0} \\
& \tilde{Z}_{0}=\tilde{R}_{0} \\
& Z_{0}=R_{0} \\
& n_{0}=0 \\
& C_{1}=0 \\
& b_{0}^{(-1)}=0 ; \quad k=0
\end{aligned}
$$

2. while $R_{k} \neq 0$ do
$d_{0}^{(k)}=<\tilde{Z}_{k}, R_{k}>_{F}$
$m_{k}=1$
$Y_{k}=A^{T} \tilde{Z}_{k}$
$V_{k}=Y_{k}$
$b_{0}^{(k)}=<Y_{k}, Z_{k}>_{F}$
3. while $b_{0}^{(k)}=0$ do
$m_{k}=m_{k}+1$
$m_{k}=m_{k}+1$
$d_{m_{k}-1}^{(k)}=<Y_{k}, R_{k}>_{F}$ $Y_{k}=A^{T} Y_{k}$
$b_{0}^{(k)}=<Y_{k}, Z_{k}>_{F}$
end while
4. if $k \neq 0$ then
$C_{k+1}=b_{0}^{(k)} / b_{0}^{(k-1)}$
end if
$T_{k}=Z_{k}$
$Z_{k+1}=-C_{k+1} Z_{k-1}$
$\tilde{T}_{k}=\tilde{Z}_{k}$
$\tilde{Z}_{k+1}=-C_{k+1} \tilde{Z}_{k-1}$
$X_{k+1}=X_{k}$
$R_{k+1}=R_{k}$
5. for $i=1, \cdots, m_{k}$ do
$U_{k}=A T_{k}$
$\beta=d_{m_{k}-i}^{(k)} / b_{0}^{(k)}$
$X_{k+1} \stackrel{m_{k}}{=} X_{k+1}+\beta T_{k}$
$R_{k+1}=R_{k+1}-\beta U_{k}$
$\gamma=-<Y_{k}, U_{k}>_{F} / b_{0}^{(k)}$
$T_{k}=U_{k}+\gamma Z_{k}$
if $i \neq 1$ then
$V_{k}=A^{T} \tilde{T}_{k}$
end if
$\tilde{T}_{k}=V_{k}+\gamma \tilde{Z}_{k}$
end for
6. $\quad Z_{k+1}=Z_{k+1}+T_{k}$
$\tilde{Z}_{k+1}=\tilde{Z}_{k+1}+\tilde{T}_{k}$
$n_{k+1}=n_{k}+m_{k}$
$k=k+1$
end while

## 4. The global BiCGSTAB algorithm.

4.1. The global BiCGSTAB algorithm. We have seen that at step $k$ the residual $R_{k}^{g b}$ and the matrix direction $P_{k}^{g b}$ produced by Gl-BCG satisfy

$$
\begin{equation*}
R_{k}^{g b}=R_{k-1}^{g b}-\alpha_{k} A P_{k-1}^{g b} \tag{4.1}
\end{equation*}
$$

and

$$
\begin{equation*}
P_{k}^{g b}=R_{k}^{g b}+\beta_{k} P_{k-1}^{g b} . \tag{4.2}
\end{equation*}
$$

The $k$-th residual of global BiCGSTAB is defined by

$$
R_{k}=\left(I-\omega_{k} A\right) S_{k}
$$

where

$$
\begin{equation*}
S_{k}=\left(I-\omega_{k-1} A\right) \ldots\left(I-\omega_{1} A\right) R_{k}^{g b} \tag{4.3}
\end{equation*}
$$

The parameter $\omega_{k}$ is selected to minimize the F-norm of $R_{k}$, so we have

$$
\omega_{k}=\frac{<S_{k}, A S_{k}>_{F}}{<A S_{k}, A S_{k}>_{F}}
$$

Using (4.1) and (4.3) we get

$$
S_{k}=R_{k-1}-\alpha_{k} A P_{k-1}
$$

where

$$
P_{k-1}=\left(I-\omega_{k-1} A\right) \ldots\left(I-\omega_{1} A\right) P_{k-1}^{g b}
$$

Now since $R_{k}^{g b}(k \geq 1)$ is F-orthogonal to the matrix Krylov subspace $\mathcal{K}_{k}\left(A^{T}, \tilde{R}_{0}\right)$ it follows from (4.3) that,

$$
<\tilde{R}_{0}, S_{k}>_{F}=0 ; \quad k \geq 1
$$

Using this orthogonality, we get

$$
\alpha_{k}=\frac{<\tilde{R}_{0}, R_{k-1}>_{F}}{<\tilde{R}_{0}, A P_{k-1}>_{F}}
$$

On the other hand, the global BiCGSTAB direction $P_{k}$ is given by

$$
P_{k}=\left(I-\omega_{k} A\right) \ldots\left(I-\omega_{1} A\right)\left[R_{k}^{g b}+\beta_{k} P_{k-1}^{g b}\right]
$$

which can be written as

$$
P_{k}=\left(I-\omega_{k} A\right)\left(S_{k}+\beta_{k} P_{k-1}\right)
$$

as well as

$$
P_{k}=\left(I-\omega_{k} A\right) Q_{k}
$$

where

$$
\begin{aligned}
Q_{k} & =S_{k}+\beta_{k} P_{k-1} \\
& =\left(I-\omega_{k-1} A\right) \ldots\left(I-\omega_{1} A\right) P_{k}^{g b}
\end{aligned}
$$

We now have to compute $\beta_{k}$ by using the fact that $P_{k}^{g b}$ is F-orthogonal to the subspace $\mathcal{K}_{k}\left(A^{T}, \tilde{R}_{0}\right)$. It follows that,

$$
<\tilde{R}_{0}, A Q_{k}>_{F}=0 ; k \geq 1
$$

Therefore

$$
\beta_{k}=-\frac{<\tilde{R}_{0}, A S_{k}>_{F}}{<\tilde{R}_{0}, A P_{k-1}>_{F}}
$$

The global BiCGSTAB algorithm is given as follows :

## ALGORITHM 5 The Gl-BiCGSTAB algorithm

Compute $R_{0}=B-A X_{0}$, where $X_{0}$ is an initial approximate solution; $P_{0}=R_{0}$ and $\tilde{R}_{0}$ arbitrary,

$$
\begin{aligned}
& \text { for } k=1,2, \ldots \\
& \quad V_{k-1}=A P_{k-1} \\
& \qquad \begin{array}{l}
S_{k}=R_{k-1}-\alpha_{k} V_{k-1}, \alpha_{k}=\frac{<\tilde{R}_{0}, R_{k-1}>_{F}}{<\tilde{R}_{0}, V_{k-1}>_{F}} \\
T_{k}=A S_{k} \\
X_{k}=X_{k-1}+\alpha_{k} P_{k-1}+\omega_{k} S_{k}, \omega_{k}=\frac{<T_{k}, S_{k}>_{F}}{<T_{k}, T_{k}>_{F}} \\
R_{k}=S_{k}-\omega_{k} T_{k} \\
P_{k}=R_{k}+\beta_{k}\left(P_{k-1}-\omega_{k} V_{k-1}\right), \text { with } \beta_{k}=-\frac{<\tilde{R}_{0}, T_{k}>_{F}}{<\tilde{R}_{0}, V_{k-1}>_{F}}
\end{array}
\end{aligned}
$$

end.
When $s=1$ the algorithm reduces to BiCGSTAB of Van der Vorst [22]. We note that global methods do not suffer from dependence of vectors during the iterations until a matrix invariant subspace is obtained (no need for deflation). However a break-down may occur if $<\tilde{R}_{0}, V_{k-1}>_{F}=0$.
4.2. A look-ahead global BiCGSTAB algorithm. The $k$-th residual produced by the global BiCGSTAB algorithm is expressed as

$$
R_{k}=\mathcal{Q}_{k}(A) \mathcal{P}_{k}(A) R_{0}
$$

where $\mathcal{Q}_{k}$ is a polynomial satisfying the following recurrence relation

$$
\mathcal{Q}_{k}(t)=\left(1-w_{k} t\right) \mathcal{Q}_{k-1}(t), \quad \mathcal{Q}_{0}(t)=1
$$

and $w_{k}$ is chosen so that $<R_{k}, R_{k}>_{F}=\left\|R_{k}\right\|_{F}^{2}$ is minimized. Let

$$
\tilde{\mathcal{P}}_{k}^{(1)}(t)=(-1)^{k} \frac{H_{k}^{(0)}}{H_{k}^{(1)}} \mathcal{P}_{k}^{(1)}(t)
$$

$\mathcal{P}_{k}^{(1)}$ is a monic formal orthogonal polynomial with respect to $c^{(1)}$. The polynomials $\mathcal{P}_{k}$ and $\mathcal{P}_{k}^{(1)}$ satisfy the recurrence relations

$$
\begin{align*}
& \mathcal{P}_{k+1}(t)=\mathcal{P}_{k}(t)-\alpha_{k+1} t \tilde{\mathcal{P}}_{k}^{(1)}(t)  \tag{4.4}\\
& \tilde{\mathcal{P}}_{k+1}^{(1)}(t)=\mathcal{P}_{k+1}(t)+\beta_{k+1} \tilde{\mathcal{P}}_{k}^{(1)}(t)
\end{align*}
$$

with $\mathcal{P}_{0}(t)=\tilde{\mathcal{P}}_{0}(t)=1$.
If the Hankel determinant $H_{k}^{(1)}$ vanishes, then the polynomials $\mathcal{P}_{k}$ and $\tilde{\mathcal{P}}_{k}^{(1)}$ do not exist and we have a true breakdown. This problem can be cured by jumping over the nonexisting polynomials and by considering only the regular ones. If $H_{k}^{(1)} \neq 0$ and the two polynomials are not of degree $k$ exactly $\left(H_{k}^{(0)}=0\right)$ then we have a ghost breakdown. This kind of breakdown is not treated in this paper.

In the sequel, we assume that $H_{k}^{(0)} \neq 0$. The $k$-th regular polynomials will be denoted by $\mathcal{P}_{k}$ and $\mathcal{P}_{k}^{(1)}$ with degree equal to $n_{k}$. The next regular polynomials $\mathcal{P}_{k+1}$ and $\tilde{\mathcal{P}}_{k+1}^{(1)}$ have degree $n_{k+1}=n_{k}+m_{k}$ where $m_{k}$ is the jump in the degrees between two successive regular polynomials; see [1] and [3].

The jump $m_{k}$ is defined by the conditions

$$
\begin{aligned}
c^{(1)}\left(t^{i} \tilde{\mathcal{P}}_{k}^{(1)}\right)=0 \quad \text { for } i=0, \ldots, n_{k}+m_{k}-2, \\
c^{(1)}\left(t^{n_{k}+m_{k}-1} \tilde{\mathcal{P}}_{k}^{(1)}\right) \neq 0
\end{aligned}
$$

Therefore the polynomials $\mathcal{P}_{k+1}$ and $\tilde{\mathcal{P}}_{k+1}^{(1)}$ are computed by the following recurrence relations

$$
\begin{align*}
& \mathcal{P}_{k+1}(t)=\mathcal{P}_{k}(t)-t \eta_{k}(t) \tilde{\mathcal{P}}_{k}^{(1)}(t)  \tag{4.5}\\
& \tilde{\mathcal{P}}_{k+1}^{(1)}(t)=\mathcal{P}_{k+1}(t)+\beta_{k+1} \tilde{\mathcal{P}}_{k}^{(1)}(t)
\end{align*}
$$

where $\mathcal{P}_{0}(t)=\tilde{\mathcal{P}}_{0}(t)=1$ and $\eta_{k}$ is a polynomial of degree $m_{k}-1$ at most. The auxiliary polynomial $\mathcal{Q}_{k}$ is of degree at most $n_{k}$ and satisfies the recurrence

$$
\begin{equation*}
\mathcal{Q}_{k+1}(t)=\left(1+w_{1}^{(k)} t+w_{2}^{(k)} t^{2}+\ldots+w_{m_{k}}^{(k)} t^{m_{k}}\right) \mathcal{Q}_{k}(t) \tag{4.6}
\end{equation*}
$$

The coefficients $\left(w_{i}{ }^{(k)}\right)_{1 \leq i \leq m_{k}}$ are chosen so that $<R_{k+1}, R_{k+1}>_{F}$ is minimized.
The jump $m_{k}$ is determined from the relations

$$
\begin{align*}
c^{(1)}\left(t^{i} \mathcal{Q}_{k} \tilde{\mathcal{P}}_{k}^{(1)}\right) & =0 \quad \text { for } i=0, \ldots, m_{k}-2,  \tag{4.7}\\
c^{(1)}\left(t^{m_{k}-1} \mathcal{Q}_{k} \tilde{\mathcal{P}}_{k}^{(1)}\right) & \neq 0
\end{align*}
$$

Let $\gamma_{i}^{(k)}, i=0, \ldots, m_{k}-1$ be the coefficients of the polynomial $\eta_{k}$ :

$$
\eta_{k}(t)=\sum_{i=0}^{m_{k}-1} \gamma_{i}^{(k)} t^{i}
$$

and set

$$
\begin{array}{ll}
b_{i}^{(k)}=c^{(1)}\left(t^{m_{k}-1+i} \mathcal{Q}_{k} \tilde{\mathcal{P}}_{k}^{(1)}(t)\right) & \text { for } i=0, \ldots, m_{k}-1 \\
d_{i}^{(k)}=c\left(t^{i} \mathcal{Q}_{k} \mathcal{P}_{k}(t)\right) & \text { for } i=0, \ldots, m_{k}-1
\end{array}
$$

In (4.5), multiplying $\mathcal{P}_{k+1}$ by $\left[t^{i} \mathcal{Q}_{k}\right], i=0, \ldots, m_{k}-1$, applying $c$ and using the orthogonality relations, we get
(4.8) $\left[\begin{array}{cccccc}b_{0}^{(k)} & & & & \\ b_{1}^{(k)} & b_{0}^{(k)} & & & 0 & \\ \vdots & b_{1}^{(k)} & \ddots & & & \\ \vdots & \vdots & \ddots & \ddots & & \\ b_{m_{k}-2}^{(k)} & b_{m_{k}-1}^{(k)} & \cdots & \ddots & b_{0}^{(k)} & \\ b_{m_{k}-1}^{(k)} & b_{m_{k}-2}^{(k)} & \cdots & \cdots & b_{1}^{(k)} & b_{0}^{(k)}\end{array}\right]\left[\begin{array}{c}\gamma_{m_{k-1}}^{(k)} \\ \gamma_{m_{k}-2}^{(k)} \\ \vdots \\ \vdots \\ \gamma_{1}^{(k)} \\ \gamma_{0}^{(k)}\end{array}\right]=\left[\begin{array}{c}d_{0}^{(k)} \\ d_{1}^{(k)} \\ \vdots \\ \vdots \\ \\ d_{m_{k}-2}^{(k)} \\ d_{m_{k}-1}^{(k)}\end{array}\right]$.

Note that, since $c^{(1)}\left(t^{m_{k}-1} \mathcal{Q}_{k} \tilde{\mathcal{P}}_{k}^{(1)}\right)=b_{0}^{(k)} \neq 0$, the matrix of the preceding linear system is nonsingular. Multiplying equation (4.5) by $t^{m_{k}-1} \mathcal{Q}_{k}$ and applying $c^{(1)}$, the coefficient $\beta_{k+1}$
is given by

$$
\begin{aligned}
\beta_{k+1} & =-\frac{c\left(t^{m_{k}} \mathcal{Q}_{k} \mathcal{P}_{k+1}\right)}{c^{(1)}\left(t^{m_{k}-1} \mathcal{Q}_{k} \tilde{\mathcal{P}}_{k}^{(1)}\right)} \\
& =-\frac{c\left(\mathcal{Q}_{k+1} \mathcal{P}_{k+1}\right)}{w_{m_{k}}^{(k)} c^{(1)}\left(t^{m_{k}-1} \mathcal{Q}_{k} \tilde{\mathcal{P}}_{k}^{(1)}\right)}
\end{aligned}
$$

It follows from

$$
\gamma_{m_{k}-1}=\frac{c\left(\mathcal{Q}_{k} \mathcal{P}_{k}\right)}{c^{(1)}\left(t^{m_{k}-1} \mathcal{Q}_{k} \tilde{\mathcal{P}}_{k}^{(1)}\right)}=\frac{d_{0}^{(k)}}{b_{0}^{(k)}}
$$

that

$$
\begin{equation*}
\beta_{k+1}=-\frac{\gamma_{m_{k}-1}}{w_{m_{k}}^{(k)}} \frac{d_{0}^{(k+1)}}{d_{0}^{(k)}} \tag{4.9}
\end{equation*}
$$

Let $Z_{k}$ and $S_{k}$ be defined as follows :

$$
\begin{aligned}
Z_{k} & =\mathcal{Q}_{k}(A) \tilde{\mathcal{P}}_{k}^{(1)}(A) R_{0} \\
S_{k} & =\mathcal{Q}_{k-1}(A) \mathcal{P}_{k}(A) R_{0}
\end{aligned}
$$

Using the relations (4.5) and (4.6), we obtain

$$
\begin{aligned}
S_{k+1} & =R_{k}-A \eta_{k}(A) Z_{k} \\
R_{k+1} & =S_{k+1}+w_{1}^{(k)} A S_{k+1}+w_{2}^{(k)} A^{2} S_{k+1}+\ldots+w_{m_{k}}^{(k)} A^{m_{k}} S_{k+1} \\
Z_{k+1} & =R_{k+1}+\beta_{k+1}\left(Z_{k}+w_{1}^{(k)} A Z_{k}+w_{2}^{(k)} A^{2} Z_{k}+\ldots+w_{m_{k}}^{(k)} A^{m_{k}} Z_{k}\right)
\end{aligned}
$$

The approximations $X_{k}$ are then computed according to

$$
X_{k+1}=X_{k}+\eta_{k}(A) Z_{k}-\left(w_{1}^{(k)} S_{k+1}+w_{2}^{(k)} A S_{k+1}+\ldots+w_{m_{k}}^{(k)} A^{m_{k}-1} S_{k+1}\right)
$$

Since the coefficients $\left(w_{i}^{(k)}\right)_{1 \leq i \leq m_{k}}$ are chosen so that $<R_{k+1}, R_{k+1}>_{F}$ is minimized, they are obtained by solving the following $m_{k} \times m_{k}$ linear system:

$$
\begin{aligned}
w_{1}^{(k)}<A^{i} S_{k+1}, A S_{k+1} & >_{F}+\ldots+w_{m_{k}}^{(k)}<A^{i} S_{k+1}, A^{m_{k}} S_{k+1}>_{F} \\
& =-<A^{i} S_{k+1}, S_{k+1}>_{F} ; \quad i=1, \ldots, m_{k}
\end{aligned}
$$

We note that since $c\left(t^{i}\right)=<\tilde{R}_{0}, A^{i} R_{0}>_{F}$, the coefficients $\left(b_{i}^{(k)}\right)$ and $\left(d_{i}^{(k)}\right)$ are given by

$$
\begin{aligned}
b_{i}^{(k)} & =<\tilde{R}_{0}, A^{i+m_{k}} Z_{k}>_{F}, \quad i=0, \ldots, m_{k}-1 \\
d_{i}^{(k)} & =<\tilde{R}_{0}, A^{i} R_{k}>_{F}, \quad i=0, \ldots, m_{k}-1
\end{aligned}
$$

The length of the jump $m_{k}$ is determined by the following relations

$$
<\tilde{R}_{0}, A^{i} Z_{k}>_{F}=0 \quad \text { for } i=1, \ldots, m_{k}-1, \text { and } \quad<\tilde{R}_{0}, A^{m_{k}} Z_{k}>_{F} \neq 0
$$

The look-ahead global BiCGSTAB algorithm is summarized as follows:
ALGORITHM 6 The Look-ahead global BiCGSTAB ( $A, B, X_{0}, \tilde{R}_{0}$ )

1. initialization

$$
\begin{aligned}
& Z_{-1}=0 \\
& R_{0}=B-A X_{0} \\
& Z_{0}=R_{0} \\
& d_{0}^{(0)}=<\tilde{R}_{0}, R_{0}>_{F} \\
& n_{0}=0 \\
& k=0
\end{aligned}
$$

2. while $R_{k} \neq 0$ do
if $d_{0}^{(0)}=0$ then stop.
$Z_{k, 0}=Z_{k}$
$Z_{k, 1}=A Z_{k, 0}$
$m_{k}=1$
$b_{0}^{(k)}=<\tilde{R}_{0}, Z_{k, 1}>_{F}$
3. while $b_{0}^{(k)}=0$ do

$$
m_{k}=m_{k}+1
$$

$$
R_{k, m_{k}-1}=A R_{k, m_{k-2}}
$$

$$
d_{m_{k}-1}^{(k)}=<\tilde{R}_{0}, R_{k, m_{k}-1}>_{F}
$$

$$
Z_{k, m_{k}}=A Z_{k, m_{k-1}}
$$

$$
b_{0}^{(k)}=<\tilde{R}_{0}, Z_{k, m_{k}}>_{F}
$$

end while
4. $\quad \gamma_{m_{k}-1}^{(k)}=d_{0}^{(k)} / b_{0}^{(k)} \quad U_{k}=Z_{k, m_{k}}$
for $i=1, \cdots, m_{k}-1$ do
$U_{k}=A U_{k}$
$b_{i}^{(k)}=<\tilde{R}_{0}, U_{k}>_{F}$
compute $\gamma_{m_{k}-i-1}^{(k)}$
end for
5. $\quad S_{k+1}=R_{k}-\gamma_{0}^{(k)} Z_{k, 1} \gamma_{1}^{(k)} Z_{k, 2}-\cdots-\gamma_{m_{k}-1}^{(k)} Z_{k, m_{k}}$
6. construct the matrices $M_{k}=\left[A S_{k+1}, \ldots, A^{m_{k}} S_{k+1}\right]^{T}\left[A S_{k+1}, \ldots, A^{m_{k}} S_{k+1}\right]$

$$
\text { and } N_{k}=\left[A S_{k+1}, \ldots, A^{m_{k}} S_{k+1}\right]^{T} S_{k+1}
$$

7. solve $M_{k} w_{k}=-N_{k} \quad$ where $\quad w_{k}=\left[w_{1}^{(k)}, w_{2}^{(k)}, \ldots, w_{m_{k}}^{(k)}\right]^{T}$
8. $\quad X_{k+1}=X_{k}+\gamma_{0}^{(k)} Z_{k, 0}+\cdots+\gamma_{m_{k}-1}^{(k)} Z_{k, m_{k}-1}-w_{1}^{(k)} S_{k+1}-\ldots-w_{m_{k}}^{(k)} A^{m_{k}-1} S_{k+1}$
$R_{k+1}=S_{k+1}+w_{1}^{(k)} A S_{k+1}+\ldots+w_{m_{k}}^{(k)} A^{m_{k}} S_{k+1}$
9. $d_{0}^{(k+1)}=<\tilde{R}_{0}, R_{k+1}>_{F}$
$\beta_{k+1}=-\frac{d_{0}^{(k+1)} \gamma_{m_{k}-1}^{(k)}}{d_{0}^{(k)} w_{m_{k}}^{(k)}}$
$Z_{k+1}=R_{k+1}+\beta_{k+1}\left(Z_{k, 0}+w_{1}^{(k)} Z_{k, 1}+\cdots+w_{m_{k}}^{(k)} Z_{k, m_{k}}\right)$
10. $n_{k+1}=n_{k}+m_{k}$
$k=k+1$
end while
11. Numerical examples. In this section, we give some experimental results. Our examples have been coded in Matlab and have been executed on a SUN SPARC workstation.

Example 1: We compared the performance of the global BCG, global BiCGSTAB and the block BCG algorithms. We used the matrices from the Harwell-Boeing collection: $A_{1}=\mathrm{PDE} 2961$
( $N=2961$ ) and $A_{2}=$ Sherman4 $(N=1024)$. The number of nonzero entries of $A_{1}$ and $A_{2}$ are $n n z\left(A_{1}\right)=14585$ and $n n z\left(A_{2}\right)=3786$. The tests were stopped as soon as $\max \left(\left\|R_{k}^{(j)}\right\|_{2} /\left\|R_{0}^{(j)}\right\|_{2}\right) \leq 10^{-7}$, for $j=1, \ldots, s$.
The initial guess $X_{0}$ was taken to be zero. We set $B=\operatorname{rand}(N, s)$, where the Matlab function rand creates an $N \times s$ random matrix with entries uniformly distributed in [0,1].

In Table 5.1, we list the CPU-time (in seconds) obtained with the three algorithms. In parentheses, we give the ratio $s \cdot t(1) / t(s)$, where $t(s)$ is the CPU-time for the global or the block method and $t(1)$ is the CPU-time obtained when applying the corresponding method for one linear system with one right-hand side. Note that the time obtained with one righthand side solver depends on which right-hand side was used. $t(1)$ was obtained by dividing the time needed for the $s$ right-hand sides by $s$. We note that a global method is effective if the indicator $s \cdot t(1) / t(s)$ is greater than 1 . The maximum number of 500 iterations was allowed for all the algorithms. As mentioned in [18], we used $\tilde{R}_{0}=A B$ for the Bl-BCG algorithm.

TABLE 5.1
Runtimes to convergence for Gl-BCG, Gl-BiCGSTAB and Bl-BCG. Matrices $A_{1}$ and $A_{2} ; s=10$ and $s=20$.

| Matrix | s | Gl-BCG | Gl-BiCGSTAB | Bl-BCG |
| :---: | :---: | :---: | :---: | :---: |
| PDE2961 | 10 | 98 | 40 | - |
| $(\mathrm{N}=2961)$ |  | $(1.39)$ | $(1.43)$ | - |
|  | 20 | 201 | 81 | - |
|  |  | $(1.43)$ | $(1.45)$ |  |
| SHERMAN4 <br> $(\mathrm{N}=1140)$ | 10 | 17 | 10 | - |
|  |  | $(1.37)$ | $(1.34)$ | - |
|  | 20 | 36 | 19 | 24 |
|  | $(1.41)$ | $(1.39)$ | $(1.35)$ |  |

Table 5.1 shows that Gl-BiCGSTAB returns the best results. Note that, for Sherman 4 and $s=20$, Bl-BCG performs better than Gl-BCG. For the matrix PDE2961, Bl-BCG failed to converge and this was also the case for Sherman4 with $s=10$.

Example 2: For this experiment we consider the matrix

$$
A=\left[\begin{array}{ccccccc}
a & 1 & & & & & \\
-1 & a & 1 & & & & \\
& -1 & a & 1 & & & \\
& & \ddots & \ddots & \ddots & & \\
& & & \ddots & \ddots & \ddots & \\
& & & & -1 & a & 1 \\
& & & & & -1 & a
\end{array}\right]
$$

with $B=I_{N, s}, X_{0}=\operatorname{rand}(N, s), \tilde{R}_{0}=I_{N, s}, N=200, s=6$ and $a=0$. In Figure 5.1, we plotted the $\log 10$ of the Frobenius norm of the residual versus the iterations. As shown in this figure, the Gl-BCG (dashed line) does not converge. Setting $\epsilon=10^{-8}$, the global Hmrz-stab(solide line) makes jumps of length $m_{k}=2$ and we obtain $n_{100}=200$ with $\left\|R_{n_{100}}\right\|_{F}=3.1410^{-11}$.
Example 3: For this experiment, the matrix $A$ is the same as in Example 2 with $N=1000$, $s=6, a=0, X_{0}=0_{N, s}$ and $\tilde{R}_{0}=R_{0}$. Figure 5.2 shows the results obtained with the

FIG. 5.1. $N=200, s=6, \epsilon=10^{-8}$

Gl-BICGSTAB (solid line) and the look-ahead Gl-BiCGSTAB (dashed line) algorithms. In this figure we plotted the Frobenius norm (in the logarithmic scale) of the residuals vesus the iterations. With $\epsilon=10^{-10}$ many jumps are detected in the look-ahead GL-BiCGSTAB algorithm. The first jump is obtained at iteration $n_{16}=16\left(n_{17}=18\right)$, the second one is detected at iteration $n_{23}=24\left(n_{24}=26\right)$. The last jump is of length $m_{k}=11$ and is detected at iteration $n_{36}=51\left(n_{37}=62\right)$.

FIG. 5.2. $N=1000, s=6$ and $\epsilon=10^{-10}$

Example 4: For this last experiment, the matrix $A=P D E 2961$ is taken from the Harwell Boeing collection $(N=2961)$. The nonzero entries of $A$ are $n n z\left(A_{4}\right)=14585$. We used
$s=10, B=I_{N, s}, X_{0}=0_{N, s}$ and $\tilde{R}_{0}=R_{0}$. Figure 5.3 reports on the results obtained with the Gl-BICGSTAB (solid line) and the look-ahead Gl-BiCGSTAB (dashed line) algorithms. We plotted the Frobenius norm of the residuals versus the iterations.

Fig. 5.3. $N=2961, s=10, \epsilon=10^{-10}$
